

Breed Longevity

AUTHOR

Jordan Gruchala

This Project studies the average longevity of seven different breed categories. Breeds are sorted according to the American Kennel Club’s breed classifications. Individual breeds are sorted according to their breed type in the table below:

Dog Breeds by Type						
herding	terrier	sporting	toy	working	non-sporting	hound
Border Collie	Border Terrier	Brittany	Papillon	Siberian Husky	Lhasa Apso	Dachshund
Australian Cattle Dog	Cairn Terrier	Welsh Springer Spaniel	Affenpinscher	Samoyed	Poodle	Whippet
Shetland Sheepdog	Miniature Schnauzer	English Cocker Spaniel	Chihuahua	Doberman Pinscher	Bichon Frise	Pharaoh Hound
Australian Shepherd	Australian Terrier	Cocker Spaniel	Pomeranian	Giant Schnauzer	Tibetan Spaniel	Beagle
Briard	West Highland White Terrier	English Springer Spaniel	Maltese	Rottweiler	Tibetan Terrier	Basset Hound
Belgian Tervuren	Bedlington Terrier	Pointer	Shih Tzu	Newfoundland	Boston Terrier	Basenji
Bouvier des Flandres	Norfolk Terrier	German Shorthaired Pointer	Yorkshire Terrier	Akita	Dalmatian	Saluki
Pembroke Welsh Corgi	Staffordshire Bull Terrier	Labrador Retriever	Brussels Griffon	Bernese Mountain Dog	French Bulldog	Greyhound
German Shepherd	Dandie Dinmont Terrier	Irish Setter	Pug	Boxer	Chow Chow	Afghan Hound
Old English Sheepdog	Scottish Terrier	Golden Retriever	English Toy Spaniel	Alaskan Malamute	Bulldog	Rhodesian Ridgeback
	Kerry Blue Terrier	Chesapeake Bay Retriever	Cavalier King Charles Spaniel	Bullmastiff		Borzoï
	Bull Terrier	Gordon Setter	Italian Greyhound	Mastiff		Irish Wolfhound
		English Setter	Pekingese	Great Dane		Bloodhound
		Flat-Coated Retriever		Saint Bernard		
		Clumber Spaniel				

For this project, I averaged the average lifespans among breeds in each AKC category, with the result being the average lifespan of each AKC category. I then present this data visually in a bar graph. This data is a useful tool for someone looking to get a dog, but worried about potential health issues. This would be especially useful as a research starting point, as potential owners can further examine why certain breed types have shorter lifespans, and can examine common health ailments by breed. It is also a useful for tool for breeders and veterinary scientists looking to identify which breed groups live the longest, allowing them to determine if there are possible genetic factors that contribute to longevity across breeds within their types.

As one can see, the terrier group has the longest lifespan. This lifespan is averaged across breeds at 12.1 years, with the minimum at 9.4, belonging to the Kerry blue terrier, and the maximum at 13.5, belonging to the Bedlington terrier. The lowest longevity belongs to the working breeds. This lifespan is averaged across breeds at 9.3 years, with the minimum at 6.5 belonging to the mastiff, and the maximum at 10.7, belonging to the Alaskan malamute. The working breeds having the lowest average lifespans aligns with common wisdom of dog breed longevity, as this group contains some of the largest dog breeds, such as great danes, saint bernards, and great pyrenees. Likewise, it is expected that the toy and terrier breeds have the longest lifespans, as these contain smaller breeds, such as the chihuahua (toy), and the Scottish terrier (terrier). Perhaps terriers have longer lifespans because they are bred with working characteristics in mind, while toy breeds are often bred with aesthetic characteristics in mind. However, the difference between the two averages is small, only the matter of two decimal points. Therefore, the difference could simply be a result of random error, and it is worth seeing if another data set ranks toys and terriers similarly.

If I were a veterinary scientist, I would study what specifically gives the terrier breeds have the greatest longevity prospects. Is there something in their genetics that makes them less predisposed to certain illnesses, or is it a matter of environment? Perhaps these breeds are more likely to go to wealthy families, where there is abundant veterinary care available. It would also be useful to study why exactly working breeds have such low longevity prospects. Again, it could be genetic, such as being predisposed to certain illnesses, or it could be environmental, such as being more likely to be abandoned.

While this data is a useful starting point, prospective dog owners and veterinary scientists should examine further if and how these differences are significant. How similar are breeds within each category, really? Do these breeds have similar health predispositions? Asking these questions will help clarify what it is that causes certain breeds to have lower life expediencies.
